#### 1 Introduction

#### 2 Relational Colour Refinement

#### 3 Relational Colour Refinement for structures with functions

#### 3.1 Naive Encoding of functions

A simple way to apply relational colour refinement to non-relational structures is, to encode the functions in the signature as a relation. Formally we transform a signature  $\sigma$  that includes function symbols to a new signature  $\sigma'$ : For every relation symbol  $R \in \sigma$ , we introduce a relation symbol  $R \in \sigma'$  with the same arity and for every function symbol  $f \in \sigma$  with arity f, we introduce a relational symbol  $f \in \sigma'$  of arity  $f \in \sigma'$ 

Semantically, a structure  $\mathfrak{A}$  of signature  $\sigma$  can then be encoded as a structure  $\mathfrak{A}'$  of signature  $\sigma'$  and with the same universe as  $\mathfrak{A}$ . For every relational symbol  $R \in \sigma$  we set  $R^{\mathfrak{A}'} := R^{\mathfrak{A}}$  and for every function symbol  $f \in \sigma$  of arity k there exists a relation symbol  $R_f \in \sigma'$  and we set  $R_f^{\mathfrak{A}} := \{(\mathbf{x}, y) : f^{\mathfrak{A}}(\mathbf{x}) = y\}$  where  $\mathbf{x}$  is a tuple of arity k.

This procedure encodes a non-relational structure as a relational one, on which Relational Colour Refinement can now be performed. As such we say, that the Naive Relational Colour Refinement (nRCR) distinguishes two structures  $\mathfrak A$  and  $\mathfrak B$  if, and only if, RCR distinguishes their naive encodings  $\mathfrak A'$  and  $\mathfrak B'$ . However, this results in a very weak logical characterisation, that does not allow nesting of terms, namely the nesting-free-fragment of  $\mathsf{GF}(\mathsf{C})$ .

**Definition 1** (nfGF(C)). Consider the definition of GF(C) given in ??. We obtain the nesting-free fragment, by allowing  $f(\mathbf{x}) = y$  as a further atomic formula. Concretely, the only allowed atomic formulae are of the form  $R(x_1, \ldots, x_\ell)$ , x = y and  $f(x_1, \ldots, x_\ell) = y$ , where f has arity  $\ell$ , free $(f(x_1, \ldots, x_\ell) = y) = \{x_1, \ldots, x_\ell\}$  and  $gd(f(\mathbf{x}) = y) = 0$ .

The remaining definitions stay the same.

**Theorem 2.** The two following statements are equivalent:

- 1. nRCR distinguishes  $\mathfrak{A}$  and  $\mathfrak{B}$ .
- 2. There exists a sentence  $\varphi \in \mathsf{nfGF}(\mathsf{C})$  such that  $\mathfrak{A} \models \varphi$  and  $\mathfrak{B} \not\models \varphi$ .
- *Proof.* 1.  $\Rightarrow$  2.: By definition,  $\mathfrak A$  and  $\mathfrak B$  are distinguished by nRCR if, and only if,  $\mathfrak A'$  and  $\mathfrak B'$  are distinguished by RCR. Using the result of [1], we obtain a sentence  $\varphi' \in \mathsf{GF}(\mathsf{C})$  that distinguishes the encoded structures. Via a structural induction on the formula, we can now translate  $\varphi'$  into a formula  $\varphi \in \mathsf{nfGF}(\mathsf{C})$  This can be achieved by expanding formulae  $R_f(x_1,\ldots,x_\ell,y)$  to  $f(x_1,\ldots,x_\ell) = y$  for function symbols  $f \in \sigma$  and letting everything else stay the same.
- $2. \Rightarrow 1.$ : When considering nfGF(C), one can find that the transformation done at the end of the first direction can be applied in reverse. This then leads to a distinguishing sentence in GF(C) and with [1] to a distinguishing colouring of the encoded structures, which by definition is a distinguishing colouring for the structures themselves.

While the above theorem results in a nice characterisation of the naive encoding, the nesting of terms is often very desired when using functions. However, it can be shown that nesting is too powerful for such a naive encoding.

Consider the two structures  $\mathfrak{A}$  and  $\mathfrak{B}$  of signature  $\sigma = \{f/1\}$  which can be seen in Figure 1. Formally they are defined as

$$\mathfrak{A} = (A = \{a_1, a_2, a_3, a_4, a_5, a_6\}, \\ f^{\mathfrak{A}} = \{ \\ a_1 \mapsto a_3, \ a_3 \mapsto a_2, \ a_2 \mapsto a_1, \\ a_4 \mapsto a_5, \ a_5 \mapsto a_6, \ a_6 \mapsto a_4 \\ \})$$

$$\mathfrak{B} = \{B = \{b_1, b_2, b_3, b_4, b_5, b_6\}, \\ f^{\mathfrak{B}} = \{ \\ b_1 \mapsto b_3, \ b_3 \mapsto b_5, \ b_5 \mapsto b_6, \\ b_6 \mapsto b_4, \ b_4 \mapsto b_2, \ b_2 \mapsto b_1 \\ \})$$

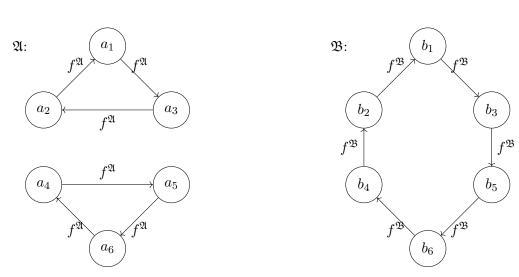

Figure 1: Two  $\sigma$ -structures  $\mathfrak A$  and  $\mathfrak B$ 

Consider the formula  $\varphi = \exists x. (f(f(f(x))) = x)$  which utilizes term nesting to find a cycle with length three. It is obvious that  $\mathfrak{A} \models \varphi$  and  $\mathfrak{B} \not\models \varphi$ . However, when encoding the two structures with the naive method described above, one finds that nRCR cannot distinguish them. Therefore, term nesting is too powerful for the naive encoding.

A method that allows for the nesting of terms will be described in the following section.

#### 3.2 Using the transitive expansion

Let

$$\mathcal{I}(n,m) = \{(k,l,p) \in [n]^3 : k+p < k+l \le n \land k+r \cdot l+p = m \text{ for some } r \in \mathbb{N}\}.$$

The set will represents the possible ways, to decompose a path into a cycle and the path to and from it. This means, that the triple  $(k, \ell, p)$  will represent a path, that has a beginning part of length k, then a cycle of length  $\ell$  and a last part that consists of the first p elements of the cycle. One can see that in a structure  $\mathfrak A$  with a unary function f and n elements, any path along of f with length m > n can be decomposed into a triple in the set  $\mathcal I(n,m)$ .

**Lemma 3.** Let  $\psi(x_1, x_2) := f^m(x_1) = x_2$ . Then there exists a formula  $\vartheta(x_1, x_2) \in \mathsf{GF}(\mathsf{C})$  such that for any  $\mathfrak A$  with  $\|\mathfrak A\| = n$  it holds

$$\mathfrak{A}, a_1, a_2 \models \psi(x_1, x_2)$$
 if, and only if,  $\mathfrak{A}, a_1, a_2 \models \vartheta(x_1, x_2)$ 

and for any  $f^{m'}(x)$  that appears in  $\vartheta$ ,  $m' \leq n$ .

*Proof.* If  $m \leq n$ , we let  $\vartheta := \psi$  and the claim follows.

Otherwise, we define

$$\vartheta(x_1, x_2) \coloneqq \bigvee_{(k,\ell,p)\in\mathcal{I}(n,m)} \zeta_{(k,\ell,p)}(x_1, x_2)$$

where

$$\zeta_{(k,\ell,p)}(x_1, x_2) := f^{k+p}(x_1) = x_2 \wedge f^k(x_1) = f^{k+\ell}(x_1)$$
$$\wedge \operatorname{E}_f^{k,\ell}(x_1)$$
$$\wedge \bigwedge_{\ell' < \ell} f^k(x_1) \neq f^{k+\ell'}(x_1)$$

and

$$E_f^{k,\ell}(t(x_1)) = \begin{cases} \top & \text{if } k = 0\\ f^{k-1}(t(x_1)) \neq f^{k-1+\ell}(t(x_1)) & \text{otherwise.} \end{cases}$$

Due to the definition of  $\mathcal{I}(n,m)$  it is obvious that only  $f^{m'}$  with  $m' \leq n$  appears.

We now proceed to the proof of the equivalence. For the purpose of readability, we will use  $f_{\mathfrak{A}}$  instead of  $f^{\mathfrak{A}}$ .

We will show that if  $\mathfrak{A}$ ,  $a_1, a_2 \models \vartheta(x_1, x_2)$ , then  $\mathfrak{A}$ ,  $a_1, a_2 \models \psi(x_1, x_2)$ . Let  $\mathfrak{A}$ ,  $a_1, a_2 \models \vartheta(x_1, x_2)$ . By definition of  $\vartheta$ , there are  $(k, \ell, p) \in \mathcal{I}(n, m)$  with  $\mathfrak{A}$ ,  $a_1, a_2 \models \zeta_{(k, \ell, p)}(x_1, x_2)$ . In particular  $f_{\mathfrak{A}}^k(a_1) = f_{\mathfrak{A}}^{k+\ell}(a_1)$ . It follows that

$$f_{\mathfrak{A}}^{k}(a_{1}) = f_{\mathfrak{A}}^{k+\ell}(a_{1}) = f_{\mathfrak{A}}^{k+2\ell}(a_{1}) = f_{\mathfrak{A}}^{k+3\ell}(a_{1}) = \dots = f_{\mathfrak{A}}^{k+r\cdot\ell}(a_{1})$$

for all  $r \in \mathbb{N}$ . By using the definition of  $\mathcal{I}(n,m)$ , we get

$$a_2 = f_{\mathfrak{A}}^{k+p}(a_1) = f_{\mathfrak{A}}^{k+r \cdot \ell + p}(a_1) = f_{\mathfrak{A}}^m(a_1).$$

From this we can deduce  $\mathfrak{A}, a_1, a_2 \models \psi(x_1, x_2)$ , where  $\psi(x_1, x_2)$  has the form  $f^m(x_1) = x_2$ .

Now we prove that if  $\mathfrak{A}, a_1, a_2 \models \psi(x_1, x_2)$ , then  $\mathfrak{A}, a_1, a_2 \models \vartheta(x_1, x_2)$ . Let  $\mathfrak{A}, a_1, a_2 \models \psi(x_1, x_2)$ . By assumption m > n and by the pigeonhole principle there have to be distinct i, j such that  $f_{\mathfrak{A}}^i(a_1) = f_{\mathfrak{A}}^j(a_1)$ . Choose such i, j such that they are lexicographically minimal.

Now choose k := i,  $\ell := j - i$  and  $p := (m - i) \mod (j - i) = (m - i) \mod \ell$ . Obviously  $(k, \ell, p) \in \mathcal{I}(n, m)$  and what remains to be shown is that  $\mathfrak{A}, a_1, a_2 \models \zeta_{(k, \ell, p)}(x_1, x_2)$ . For that, we consider the parts of the conjunction and show for each one that it is satisfied.

 $f^{k+p}(x_1) = x_2$ : We use the fact that  $a = b \mod c \Leftrightarrow b = r \cdot c + a$  for some  $r \in \mathbb{N}$ . Then

$$f_{\mathfrak{A}}^{k+p}(a_1) = f_{\mathfrak{A}}^{i+(m-i)-r\cdot\ell}(a_1) = f_{\mathfrak{A}}^{i+r\cdot\ell+m-i-r\cdot\ell}(a_1) = f_{\mathfrak{A}}^m(a_1) = a_2.$$

Therefore  $\mathfrak{A}, a_1, a_2 \models f^{k+p}(x_1) = x_2.$ 

 $f^k(x_1) = f^{k+\ell}(x_1)$ : Consider that

$$f^k_{\mathfrak{A}}(a_1) = f^i_{\mathfrak{A}}(a_1) = f^j_{\mathfrak{A}}(a_1) = f^{j+i-i}_{\mathfrak{A}}(a_1) = f^{i+j-i}_{\mathfrak{A}}(a_1) = f^{k+\ell}_{\mathfrak{A}}(a_1).$$

This leads to  $\mathfrak{A}, a_1, a_2 \models f^k(x_1) = f^{k+\ell}(x_1).$ 

 $\mathrm{E}_f^{k,\ell}(x_1)$ : This has to be satisfied, otherwise  $f_{\mathfrak{A}}^{k-1}(a_1)=f_{\mathfrak{A}}^{k-1+\ell}(a)$ , but then  $(k-1,\ell)$  would be lexicographically smaller than (i,j).

The same reasoning applies to  $\bigwedge_{\ell' < \ell} f^k(x_1) \neq f^{k+\ell'}(x_1)$ . If it weren't satisfied, there would be a (i, j') with j' < j and  $f^i_{\mathfrak{A}}(a_1) = f^{i+j'}_{\mathfrak{A}}(a_1)$  which would be lexicographically smaller than (i, j).

Thus we have shown that every subformula of the conjunction and therefore the formula is being fulfilled.  $\Box$ 

The above proof allows for the translation of formulae  $f^m(x) = y$  to a formula  $\vartheta(x, y)$  that is equivalent for structures with n elements. A natural extension would be, to allow alternation of functions, for example formulae like  $g^m(f^{m'}(x)) = y$ . This is also possible and will be proved in the following proof.

**Lemma 4.** Let  $\psi(x_1, x_2) := t(x_1) = x_2$  be an atomic formula. Then there exists a formula  $\vartheta_t(x_1, x_2) \in \mathsf{GF}(\mathsf{C})$ , such that for any structure (of a fitting signature)  $\mathfrak{A}$  with  $\|\mathfrak{A}\| = n$  it holds

$$\mathfrak{A}, a_1, a_2 \models \psi(x_1, x_2)$$
 if, and only if,  $\mathfrak{A}, a_1, a_2 \models \vartheta_t(x_1, x_2)$ .

Furthermore,  $\vartheta_t(x_1, x_2)$  is of the form  $\vartheta_t(x_1, x_2) = \bigvee \Phi(x_1, x_2)$  where all  $\varphi(x_1, x_2) \in \Phi(x_1, x_2)$  are of the form

$$t'(x_1) = x_2 \wedge \bigwedge \Psi(x_1)$$

for some term  $t'(x_1)$ , and for every  $f^m(s(x))$  that appears in  $\vartheta_t$ ,  $m \leq n$ .

*Proof.* We prove this via an induction on the term  $t(x_1)$ .

**Base case:** If  $t(x_1) := f^m(x_1)$  for a unary function symbol f and  $m \in \mathbb{N}$ , we use the formula constructed in the proof of Theorem 3. It can easily be verified that it is in the correct form.

**Inductive step:** Assume that  $t(x_1) := g^m(s(x_1))$  for a unary function symbol  $g, m \in \mathbb{N}$  and term s. By induction hypothesis, we have a formula  $\vartheta_s(y_1, y_2) = \bigvee \Phi_s(y_1, y_2)$  in the above defined form with  $\mathfrak{A}, a_1, a_2 \models s(y_1) = y_2$  if, and only if,  $\mathfrak{A}, a_1, a_2 \models \vartheta_s(y_1, y_2)$ .

If  $m \leq n$ , we set

$$\vartheta_t(x_1, x_2) = \bigvee \Phi'(x_1, x_2),$$

where  $\Phi'(x_1, x_2) := \{g^m(t'(y_1/x_1)) = x_2 \land \bigwedge \Psi(y_1/x_1) : t'(y_1) = y_2 \land \bigwedge \Psi(y_1) \in \Phi_s(y_1, y_2)\}.$ Now assume m > n.

Then we set

$$\vartheta_t(x_1, x_2) = \bigvee_{(k,\ell,p) \in \mathcal{I}(n,m)} \bigvee \Phi'_{(k,\ell,p)}(x_1, x_2),$$

where

$$\Phi'_{(k,\ell,p)} := \{ g^{k+p}(t'(y_1/x_1)) = x_2 \wedge g^k(t'(y_1/x_1)) = g^{k+\ell}(t'(y_1/x_1)) \\
\wedge \operatorname{E}_g^{k,\ell}(t'(y_1/x_1)) \wedge \bigwedge_{\ell' < \ell} g^k(t'(y_1/x_1)) \neq g^{k+\ell'}(t'(y_1/x_1)) \\
\wedge \Psi(y_1/x_1) : t'(y_1) = y_2 \wedge \bigwedge \Psi(y_1) \in \Phi_s(y_1, y_2) \}$$

By using the above definitions, we get  $\mathfrak{A}, a_1, a_2 \models s(y_1) = y_2$  if, and only if,  $\mathfrak{A}, a_1, a_2 \models \varphi_s(y_1, y_2)$  for some  $\varphi_s \in \Phi_s$  where  $\varphi_s(y_1, y_2)$  is of the form  $t'(y_1) = y_2 \land \bigwedge \Psi(y_1)$ . Therefore

$$\mathfrak{A}, a_1, a_2 \models s(y_1) = y_2 \text{ if, and only if, } \mathfrak{A}, a_1, a_2 \models t'(y_1) = y_2 \land \bigwedge \Psi(y_1).$$
 (1)

We now proof that

$$\mathfrak{A}, a_1, a_2 \models t(x_1) = x_2$$
 if, and only if,  $\mathfrak{A}, a_1, a_2 \models \vartheta_t(x_1, x_2)$ .

Assume  $m \leq n$ . Let  $\mathfrak{A}, a_1, a_2 \models \vartheta_t$ . Then there is some  $\varphi(x_1, x_2) := g^m(t'(y_1/x_1)) = x_2 \land \bigwedge \Psi(y_1/x_1)$  such that  $\mathfrak{A}, a_1, a_2 \models \varphi(x_1, x_2)$ . We then get

$$\mathfrak{A}, a_1, a_2 \models g^m(t'(y_1/x_1)) = x_2 \land \bigwedge \Psi(y_1/x_1)$$

$$\Leftrightarrow \mathfrak{A}, a_1, a_2, a_3 \models g^m(x_3) = x_2 \land \bigwedge \Psi(y_1/x_1) \land t'(y_1/x_1) = x_3 \text{ for all } a_3 \in A$$

$$\stackrel{Equation\ (1)}{\Leftrightarrow} \mathfrak{A}, a_1, a_2, a_3 \models g^m(x_3) = x_2 \land s(x_1) = x_3 \text{ for all } a_3 \in A$$

$$\Leftrightarrow \mathfrak{A}, a_1, a_2 \models g^m(s(x_1)) = x_2.$$

Now let m > n. Then there is a

$$\varphi(x_1, x_2) := g^{k+p}(t'(y_1/x_1)) = x_2 \wedge g^k(t'(y_1/x_1)) = g^{k+l}(t'(y_1/x_1))$$

$$\wedge \operatorname{E}_g^{k,l}(t'(y_1/x_1)) \wedge \bigwedge_{\ell' < \ell} g^k(t'(y_1/x_1)) \neq g^{k+\ell'}(t'(y_1/x_1))$$

$$\wedge \Psi(y_1/x_1)$$

for some  $(k, \ell, p) \in \mathcal{I}(n, m)$  with  $\mathfrak{A}, a_1, a_2 \models \varphi(x_1, x_2)$ . And now

$$\mathfrak{A}, a_{1}, a_{2} \models \psi(x_{1}, x_{2})$$

$$\Leftrightarrow A, a_{1}, a_{2}, a_{3} \models g^{k+p}(x_{3}) = x_{2} \wedge g^{k}(x_{3})) = g^{k+l}(x_{3})$$

$$\wedge \operatorname{E}_{g}^{k,l}(x_{3}) \wedge \bigwedge_{\ell' < \ell} g^{k}(x_{3}) \neq g^{k+\ell'}(x_{3})$$

$$\wedge \Psi(y_{1}/x_{1}) \wedge t'(y_{1}/x_{1}) = x_{3} \text{ for all } a_{3} \in A$$

$$\stackrel{Theorem 3}{\Leftrightarrow} \mathfrak{A}, a_{1}, a_{2}, a_{3} \models g^{m}(x_{3}) = x_{2} \wedge t'(y_{1}/x_{1}) = x_{3} \wedge \Psi(y_{1}/x_{1}) \text{ for all } a_{3} \in A$$

$$\stackrel{Equation (1)}{\Leftrightarrow} \mathfrak{A}, a_{1}, a_{2}, a_{3} \models g^{m}(x_{3}) = x_{2} \wedge s(x_{1}) = x_{3} \text{ for any } a_{3} \in A$$

$$\Leftrightarrow \mathfrak{A}, a_{1}, a_{2} \models g^{m}(s(x_{1})) = x_{2}.$$

The other direction follows in both cases, as only equivalent steps have been used and it is obvious that the disjunction of a set is being fulfilled, if a formula of the set is satisfied.

Therefore we have finished the proof.

A corollary of the above lemma is that the same statement holds for an arbitrary relation, instead of equality.

**Corollary 5.** Let  $\psi(x_1, \ldots, x_m) := R(t_1(x_1), \ldots, t_m(x_m))$  be an atomic formula. Then there exists a formula  $\vartheta_{\psi} \in \mathsf{GF}(\mathsf{C})$ , such that for any given structure (of fitting signature)  $\mathfrak{A}$  with  $\|\mathfrak{A}\| = n$  it holds

$$\mathfrak{A}, a_1, \ldots, a_m \models \psi(x_1, \ldots, x_m)$$
 if, and only if,  $\mathfrak{A}, a_1, \ldots, a_m \models \vartheta_{\psi}(x_1, \ldots, x_m)$ .

Furthermore,  $\vartheta_{\psi}(x_1,\ldots,x_m)$  is of the form  $\bigvee \Phi(x_1,\ldots,x_m)$  where all  $\varphi \in \Phi$  are of the form

$$R(t'_1(x_1),\ldots,t'_m(x_m)) \wedge \bigwedge \Psi_1(x_1) \wedge \cdots \wedge \bigwedge \Psi_m(x_m),$$

and for every  $f^m(s(x))$  that appear in  $\vartheta_{\psi}$ , where f is a unary function symbol and s is a term,  $m \leq n$ . Proof. Let  $\mathfrak{A}, a_1, \ldots, a_m \models \psi(x_1, \ldots, x_m)$ . This is equivalent to

$$\mathfrak{A}, a_1, \ldots, a_m, b_1, \ldots, b_m \models R(b_1, \ldots, b_m) \land t_1(x_1) = b_1 \land \cdots \land t_m(x_m) = b_m$$

for arbitrary  $b_1, \ldots, b_m \in A$ . By applying the previous lemma, we get the equivalent statement

$$\mathfrak{A}, a_1, \dots, a_m, b_1, \dots, b_m \models R(y_1, \dots, y_m) \land \bigvee_{i_1} \left( t'_{1,i_1}(x_1) = y_1 \land \bigwedge \Psi_{1,i_1}(x_1) \right)$$

$$\land \dots$$

$$\land \bigvee_{i_m} \left( t'_{m,i_m}(x_m) = y_m \land \bigwedge \Psi_{m,i_m}(x_m) \right).$$

Through distribution of boolean formulae we get

$$\mathfrak{A}, a_1, \dots, a_m, b_1, \dots, b_m \models \bigvee_{i_1} \dots \bigvee_{i_m} (R(y_1, \dots, y_m) \wedge t'_{1, i_1}(x_1) = y_1 \wedge \bigwedge \Psi_{1, i_1}(x_1)$$

$$\wedge \dots$$

$$\wedge t'_{m, i_m}(x_m) = y_m \wedge \bigwedge \Psi_{m, i_m}(x_m).$$

Finally, we can resubstitute variables and get

$$\mathfrak{A}, a_1, \dots, a_m \models \bigvee_{i_1} \dots \bigvee_{i_m} R(t'_{1,i_1}(x_1), \dots, t'_{m,i_m}(x_m)) \wedge \bigwedge \Psi_{1,i_1}(x_1) \wedge \dots \wedge \bigwedge \Psi_{m,i_m}(x_m) =: \vartheta_{\psi}(x_1, \dots, x_m).$$

One can see that  $\vartheta_{\psi}$  is of the correct form. The equality follows from the fact that only equivalences have been used to derive  $\vartheta_{\psi}$  from  $\psi$ .

To obtain our characterising result for structures with (unary) functions, we have to define how the functions should be encoded.

**Definition 6** (Transitive Expansion). Let  $\sigma := \sigma_{\text{Rel}} \dot{\cup} \sigma_{\text{Func}}$  be a signature with relation symbols  $\sigma_{\text{Rel}}$  and unary function symbols  $\sigma_{\text{Func}}$  and let  $\mathfrak{A}$  be a structure of signature  $\sigma$  with  $\|\mathfrak{A}\| = n$ . For readability, we define the family of sets Alters $_n^0(\sigma) := \emptyset$  and

$$\operatorname{Alters}_{n}^{k}(\sigma) := \operatorname{Alters}_{n}^{k-1}(\sigma) \cup \{f_{1}^{m_{1}} f_{2}^{m_{2}} \dots f_{k}^{m_{k}} : f_{1} f_{2} \dots f_{k} \in (\sigma_{\operatorname{Func}})^{k}, 0 \leq m_{i} \leq n \text{ for } 1 \leq i \leq k\}$$

For an arbitrary  $k \in \mathbb{N}$ , we define the transitive expansion with alternation depth k as a structure  $\widetilde{\mathfrak{A}}$  of signature  $\widetilde{\sigma}$ , where

$$\widetilde{\sigma} := \sigma_{\mathrm{Rel}} \dot{\cup} \{ F_{\alpha} : \alpha \in \mathrm{Alters}_{n}^{k}(\sigma) \}$$

and the  $F_{\alpha}$  are binary relations. Semantically, we have

$$F_{\alpha}^{\widetilde{\mathfrak{A}}} := \{(a,b) : \alpha^{\mathfrak{A}}(a) = b\}.$$

We now can define the algorithm for relational colour refinement for (unary) functions.

**Definition 7** (RCR for structures with unary functions). Let  $\sigma$  be a signature with relation and unary function symbols and let  $\mathfrak{A}$  and  $\mathfrak{B}$  be structures of signature  $\sigma$ .

We say that  $\mathfrak{A}$  and  $\mathfrak{B}$  are being distinguished by RCR with alternation depth k (RCR<sub>k</sub>), if  $\|\mathfrak{A}\| \neq \|\mathfrak{B}\|$  or the transitive expansions with alternation depth k,  $\widetilde{\mathfrak{A}}$  and  $\widetilde{\mathfrak{B}}$ , are being distinguished by RCR.

To show that this definition may be sensible, we want to execute RCR<sub>1</sub> on the structures  $\mathfrak{A}$  and  $\mathfrak{B}$  from Figure 1. First we compute  $\tilde{\sigma}$  as  $\{F_{f^i}: 0 \leq i \leq 6\}$  and by performing the translation we obtain:

$$\begin{split} \widetilde{\mathfrak{A}} &= (A, F_{f^0}^{\widetilde{\mathfrak{A}}} = \{(a_1, a_1), (a_2, a_2), (a_3, a_3), (a_4, a_4), (a_5, a_5), (a_6, a_6)\}, \\ &F_{f^1}^{\widetilde{\mathfrak{A}}} = \{(a_1, a_3), (a_2, a_1), (a_3, a_2), (a_4, a_5), (a_5, a_6), (a_6, a_4)\}, \\ &F_{f^2}^{\widetilde{\mathfrak{A}}} = \{(a_1, a_2), (a_2, a_3), (a_3, a_1), (a_4, a_6), (a_5, a_4), (a_6, a_5)\}, \\ &F_{f^3}^{\widetilde{\mathfrak{A}}} = \{(a_1, a_1), (a_2, a_2), (a_3, a_3), (a_4, a_4), (a_5, a_5), (a_6, a_6)\}, \\ &F_{f^4}^{\widetilde{\mathfrak{A}}} = \{(a_1, a_3), (a_2, a_1), (a_3, a_2), (a_4, a_5), (a_5, a_6), (a_6, a_4)\}, \\ &F_{f^5}^{\widetilde{\mathfrak{A}}} = \{(a_1, a_2), (a_2, a_3), (a_3, a_1), (a_4, a_6), (a_5, a_4), (a_6, a_5)\}, \\ &F_{f^6}^{\widetilde{\mathfrak{A}}} = \{(a_1, a_1), (a_2, a_2), (a_3, a_3), (a_4, a_4), (a_5, a_5), (a_6, a_6)\}) \end{split}$$

and

$$\begin{split} \widetilde{\mathfrak{B}} &= (B, F_{f^0}^{\widetilde{\mathfrak{B}}}) = \{(a_1, a_1), (a_2, a_2), (a_3, a_3), (a_4, a_4), (a_5, a_5), (a_6, a_6)\}, \\ &F_{f^1}^{\widetilde{\mathfrak{B}}} = \{(a_1, a_3), (a_2, a_1), (a_3, a_5), (a_4, a_2), (a_5, a_6), (a_6, a_4)\}, \\ &F_{f^2}^{\widetilde{\mathfrak{B}}} = \{(a_1, a_5), (a_2, a_3), (a_3, a_6), (a_4, a_1), (a_5, a_4), (a_6, a_2)\}, \\ &F_{f^3}^{\widetilde{\mathfrak{B}}} = \{(a_1, a_6), (a_2, a_5), (a_3, a_4), (a_4, a_3), (a_5, a_2), (a_6, a_1)\}, \\ &F_{f^4}^{\widetilde{\mathfrak{B}}} = \{(a_1, a_4), (a_2, a_6), (a_3, a_2), (a_4, a_5), (a_5, a_1), (a_6, a_3)\}, \\ &F_{f^5}^{\widetilde{\mathfrak{B}}} = \{(a_1, a_2), (a_2, a_4), (a_3, a_1), (a_4, a_6), (a_5, a_3), (a_6, a_5)\}, \\ &F_{f^6}^{\widetilde{\mathfrak{B}}} = \{(a_1, a_1), (a_2, a_2), (a_3, a_3), (a_4, a_4), (a_5, a_5), (a_6, a_6)\}) \end{split}$$

By using [1], we know that RCR distinguishes  $\widetilde{\mathfrak{A}}$  and  $\widetilde{\mathfrak{B}}$  if, and only if, there is a formula  $\widetilde{\varphi} \in \mathsf{GF}(\mathsf{C})$  of signature  $\widetilde{\sigma}$  that distinguishes them. Notice that  $F_{f^0}^{\widetilde{\mathfrak{A}}} = F_{f^0}^{\widetilde{\mathfrak{A}}} = F_{f^0}^{\widetilde{\mathfrak{A}}}$ ,  $F_{f^1}^{\widetilde{\mathfrak{A}}} = F_{f^2}^{\widetilde{\mathfrak{A}}}$  and  $F_{f^2}^{\widetilde{\mathfrak{A}}} = F_{f^5}^{\widetilde{\mathfrak{A}}}$ , while only  $F_{f^0}^{\widetilde{\mathfrak{A}}} = F_{f^6}^{\widetilde{\mathfrak{A}}}$ . Therefore the sentence

$$\exists^{\geq 6}(x,y).\left(F_{f^1}(x,y)\wedge F_{f^4}(x,y)\right)\in\mathsf{GF}(\mathsf{C})$$

is satisfied by  $\widetilde{\mathfrak{A}}$ , but not  $\widetilde{\mathfrak{B}}$ .

We see, that this procedure distinguishes structures, that were not distinguished by nRCR. To formalise this, we want to characterise this algorithm logically, as well as combinatorially.

#### 3.2.1 Logical characterisation of $RCR_k$

**Definition 8** (Alternation bounded GF(C)). The fragment of GF(C) with an alternation bound of k ( $GF(C)_k$ ) is GF(C) with the constraint that for all formulae  $\varphi \in GF(C)_k$  of signature  $\sigma$  and every term t that appears in  $\varphi$ , there is an  $n \in \mathbb{N}$  and an  $\alpha \in Alters_n^k(\sigma)$  such that  $\alpha = t$ . Atomic formulae are defined as usual, that is, the formulae  $R(t_1(x_1), t_2(x_2), \ldots, t_n(x_n))$  and  $t_1(x_1) = t_2(x_2)$  for terms  $t_1, t_2, \ldots, t_n$  and variables  $x_1, x_2, \ldots, x_n$  are atomic formulae.

**Theorem 9.** Let  $\mathfrak{A}$  and  $\mathfrak{B}$  be two structures of the same signature  $\sigma$  with relation and unary function symbols and let  $k \in \mathbb{N}$  The two following statements are equivalent:

- 1. RCR<sub>k</sub> distinguishes  $\mathfrak{A}$  and  $\mathfrak{B}$ .
- 2. There exists a sentence  $\varphi \in GF(C)_k$  such that  $\mathfrak{A} \models \varphi$  and  $\mathfrak{B} \not\models \varphi$ .

*Proof.* We prove that 1. implies 2.. Let  $\mathfrak{A}$  and  $\mathfrak{B}$  be distinguished by  $RCR_k$ . If they are of different sizes, assume without loss of generality that

$$\|\mathfrak{A}\| = n > n' = \|\mathfrak{B}\|.$$

Then define  $\varphi := \exists^{\geq n} x. \top \in \mathsf{GF}(\mathsf{C})_k$ , which obviously distinguishes the structures.

Now assume  $\|\mathfrak{A}\| = \|\mathfrak{B}\| = n$ . By definition, RCR distinguishes  $\widetilde{\mathfrak{A}}$  and  $\widetilde{\mathfrak{B}}$ . When using the proof from [1], we obtain a formula  $\widetilde{\varphi} \in \mathsf{GF}(\mathsf{C})$  of signature  $\widetilde{\sigma}$  that distinguishes the expansions. This formula  $\widetilde{\varphi}$  can then be translated to a formula  $\varphi \in \mathsf{GF}(\mathsf{C})_k$  of signature  $\sigma$ .

For every atomic subformula  $R(\mathbf{x})$ , where  $R \in \sigma_{\text{Rel}}$ , let the formula stay the same. For every atomic subformla  $F_{\alpha}(x,y)$ , where  $\alpha \in \text{Alters}_{n}^{k}(\sigma)$ , replace it by the formula  $\alpha(x) = y$ . Obviously, if a structure's expansion satisfied  $\widetilde{\varphi}$ , it also satisfies  $\varphi$  and vice versa.

Therefore, we get a formula  $\varphi \in \mathsf{GF}(\mathsf{C})_k$  that distinguishes  $\mathfrak{A}$  and  $\mathfrak{B}$ . Now we prove that  $\mathcal{Z}$ . implies 1.. Let  $\varphi \in \mathsf{GF}(\mathsf{C})_k$  such that  $\mathfrak{A} \models \varphi$  and  $\mathfrak{B} \not\models \varphi$ . Our approach will be, to transform  $\varphi$  to a formula  $\widetilde{\varphi}$  that only uses symbols from  $\widetilde{\sigma}$ . However, through the transformation, we introduce a syntactical form that is not allowed in the definition of  $\mathsf{GF}(\mathsf{C})$ . Therefore we will define a new class of formulae, called conjunctive- $\mathsf{GF}(\mathsf{C})$ , of which  $\widetilde{\varphi}$  will be an element of. Furthermore, we will derive a winning strategy of the Guarded Game for the Spoiler (cf. [1], Lemma 5.7), which then will conclude the proof.
